

Intro

- Interpreter used to convert written code to machine code
- Use py charm or vs code
- For vs code, install the extension.
- Install interpreter from python website.
- For pycharm, install it from jetbrains.
- Create a new project and select the interpreter.
- `print('Hello')`
- `print("Hello")` both runs
- For comments use `#` before the line
- Variable → container for a value. Behaves as if it was the value it contains.
- Variables can be of string, integer, float, boolean types.
- Each variable should have a unique name
- To assign a value to a variable, use assignment operator `=`

Variables

String →

- series of text. Use single or double quotes
- `First_name = "Bro"`
- `print(First_name)` returns Bro
- `print("First_name")` returns First_name
- `print(f"Hello {First_name}")` returns Hello Bro
- The above is an f-string. Template literal and string literal used in Js.
- `f` → means format
- Strings can include numbers which are considered as characters.

Integers →

- An integer is a whole number.
- `age = 25` → correct way of declaring integer
- `age = "25"` → considered as a string
- `print(f"You are {age} years old")` returns You are 25 years old
- `Age = 25`
